University of Wisconsin, Madison and University of Pennsylvania

Abstract

The method of regularization with the Gaussian reproducing kernel is popular in the machine learning literature and successful in many practical applications. In this paper we consider the periodic version of the Gaussian kernel regularization. We show in the white noise model setting, that in function spaces of very smooth functions, such as the infinite order Sobolev space and the space of analytic functions, the method under consideration is asymptotically minimax; in finite order Sobolev spaces, the method is rate optimal, and the efficiency in terms of constant when compared with the minimax estimator is reasonably high. The smoothing parameters in the periodic Gaussian regularization can be chosen adaptively without loss of asymptotic efficiency. The results derived in this paper give a partial explanation of the success of the Gaussian reproducing kernel in practice. Simulations are carried out to study the finite sample properties of the periodic Gaussian regularization.

Key words and phrases. Asymptotic minimax risk, Gaussian reproducing kernel, nonparametric estimation, rate of convergence, Sobolev spaces, white noise model.

1 Introduction

The method of regularization is a popular approach for nonparametric function estimation. Let $f$ be the nonparametric function to be estimated. The method of regularization takes the form

$$\min_{f \in \mathcal{F}} [L(f, \text{data}) + \lambda J(f)].$$

(1)

where $L$ is the empirical loss, often taken to be the negative log-likelihood, and $J(f)$ is the penalty functional, usually a quadratic functional corresponding to a norm or semi-norm of a reproducing kernel Hilbert space $\mathcal{F}$. Most often the penalty functional is chosen so that smoother functions incur smaller penalty. The smoothing parameter $\lambda$ controls the tradeoff

\textsuperscript{1}Supported in part by NSF Grant DMS-0134987
\textsuperscript{2}Supported in part by NSF Grant DMS-9971751
between minimizing the empirical loss and obtaining a smooth solution. For a concrete example, let us look at the regression model:

$$y_j = f(x_j) + \delta_j, \quad j = 1, \ldots, n,$$

(2)

where $x_j \in R$, $j = 1, \ldots, n$, are the regression inputs, $y_j$'s are the responses, and $\delta_j$'s are independent $N(0, 1)$ noises. In this case we may take $L(f, \text{data}) = \sum_{j=1}^{n}(y_j - f(x_j))^2$ in the method of regularization (1).

The reproducing kernel Hilbert space $\mathcal{F}$ is typically of infinite dimension. In many situations including the regression and the generalized regression, when the penalty functional $J(f)$ is a norm over $\mathcal{F}$, the theory of reproducing kernel Hilbert space guarantees that the solution to (1) over $\mathcal{F}$ falls in the finite dimensional space spanned by $\{K(x_j, \cdot), j = 1, \ldots, n\}$, where $K(\cdot, \cdot)$ is the reproducing kernel corresponding to $J(f)$. See Wahba (1990) for an introduction to the theory of reproducing kernels. Therefore we can write the solution as $\hat{f} = \sum_{j=1}^{n} c_j K(x, x_j)$. The minimization problem can then be solved in this finite dimensional space.

The smoothing spline well-known in the nonparametric statistics literature is an example of the method of regularization. In the smoothing spline the reproducing kernel Hilbert space $\mathcal{F}$ is a Hilbert Sobolev space and the penalty functional $J(f)$ is the norm or semi-norm of the space, such as $\int [f^{(m)}(x)]^2 dx$. The commonly used cubic smoothing spline corresponds to the case $m = 2$. The reproducing kernel of the Hilbert Sobolev space was given in Wahba (1990).

The method of regularization has also been popular in the machine learning literature. Examples include regularization networks and more recently, support vector machines. See, for example, Girosi, Jones, and Poggio (1993), Smola, Schölkopf, and Müller (1998), Wahba (1999), Evgeniou, Pontil, and Poggio (1999). One reproducing kernel that is particularly popular in the machine learning literature is the Gaussian reproducing kernel (commonly referred to as the Gaussian kernel in the machine learning literature, not to be confused with the Gaussian kernel used in kernel smoothing in the nonparametric statistics literature). Let $G(r) = (2\pi)^{-1/2} \omega^{-1} \exp(r^2/(2\omega^2))$ be the density function of $N(0, \omega^2)$. The Gaussian reproducing kernel has the form $G(s, t) \equiv G(s - t)$. This is a common example of the translation invariant reproducing kernels popular in machine learning. It is known (Girosi, Jones and Poggio, 1993; Smola, Schölkopf, and Müller, 1998) that the Gaussian reproducing kernel corresponds to the penalty functional (up to a constant)

$$J_g(f) = \sum_{m=0}^{\infty} \frac{\omega^{2m}}{2^{m}m!} \int_{-\infty}^{\infty} [f^{(m)}(x)]^2 dx.$$

(3)

Smola, Schölkopf, and Müller (1998) introduced the periodic Gaussian reproducing kernel for estimating $2\pi$-periodic functions in $[-\pi, \pi]$ as the reproducing kernel corresponding to
the penalty functional
\[ J_0(f) = \sum_{m=0}^{\infty} \frac{\omega^{2m}}{2^{m}m!} \int_{-\pi}^{\pi} |(f^{(m)})^2(x)| dx. \] (4)

From (3) and (4), it is clear that the two reproducing kernels are closely related. The connection between the two reproducing kernels will be clearer when we consider the computation with the periodic Gaussian reproducing kernel in Section 5.

Many researchers in machine learning have derived upper bounds of the generalization performance of the method of regularization with the Gaussian or periodic Gaussian reproducing kernels. See Williamson, Smola, and Schölkopf (2001) and the references therein. However, while popular in the machine learning literature, and successful in many practical applications, the statistical asymptotic properties of the method of regularization with the Gaussian or periodic Gaussian reproducing kernels have not been studied systematically. In this paper, we study the asymptotic properties of the method of regularization with the periodic Gaussian reproducing kernel in nonparametric function estimation problems, and derive the asymptotic risk (up to constants) of the method of regularization with the periodic Gaussian reproducing kernel. We choose to work with the periodic Gaussian reproducing kernel because it allows a detailed asymptotic analysis. We believe the results obtained in this paper should also give insights on the statistical properties of the Gaussian reproducing kernel.

Motivated by the equivalence results of Brown and Low (1996) for Gaussian nonparametric regression and Nussbaum (1996) for density estimation, (see also Golubev and Nussbaum, 1998, for spectral density estimation; Grama and Nussbaum, 1997, for nonparametric generalized linear regression), we first look at the white noise problem:

\[ Y_n(t) = \int_{-\pi}^{t} f(u) du + n^{-1/2} B(t), \quad t \in [-\pi, \pi], \] (5)

where \( B(t) \) is a standard Brownian motion on \([-\pi, \pi]\) and we observe \( Y_n = (Y_n(t), -\pi \leq t \leq \pi) \). We consider the situation where the function \( f \) belongs to a certain function ellipsoid of the form

\[ \{ f : f(t) = \sum_{\ell=0}^{\infty} \theta_\ell \phi_\ell(t), \sum_{\ell=0}^{\infty} \rho_\ell \theta_\ell^2 \leq Q \}, \] (6)

for some positive sequence \( \{\rho_\ell, \ell = 0, 1, \ldots\} \). Here \( \{\phi_\ell(t) = (2\pi)^{-1/2} \phi_{2\ell-1}(t) = \pi^{-1/2} sin(\ell t), \phi_{2\ell}(t) = \pi^{-1/2} cos(\ell t)\} \) is the classical trigonometric basis in \( L_2(-\pi, \pi) \) and \( \theta_\ell = (f, \phi_\ell) \) is the corresponding Fourier coefficient, where \( (f, \phi) = \int_{-\pi}^{\pi} f(t) \phi(t) dt \) denotes the usual inner product in \( L_2(-\pi, \pi) \).

The commonly considered Sobolev ellipsoid \( H^m(Q) \) corresponds to the sequence \( \rho_0 = 1, \rho_{2\ell-1} = \rho_{2\ell} = \ell^{2m} + 1 \) in (6). This is the \( m \)-th order Sobolev space of periodic functions on
\([-\pi, \pi]\). An alternative definition of \(H^m(Q)\) is

\[
H^m(Q) = \{ f \in L^2(-\pi, \pi) : f \text{ is } 2\pi\text{-periodic, } \int_{-\pi}^{\pi} [f(t)]^2 + [f^{(m)}(t)]^2 dt \leq Q \}. \tag{7}
\]

Therefore the \(m\)-th order Sobolev space consists of functions that possess \(m\)-th order smoothness. The order of smoothness is determined by the rate at which the sequence of \(\rho_i\)'s increases. In the Sobolev space case, the rate is of polynomial order.

Another function space that has been considered in the literature is the space of analytic functions. An ellipsoid of analytic functions \(A_\alpha(Q)\) corresponds to (6) with the exponentially increasing sequence \(\rho_\ell = \exp(\alpha \ell)\), where \(\alpha\) is a positive constant. Such a function space can be motivated by considering the Fourier series in complex exponentials and considering the domain in which the function is analytical. For details, see Johnstone (1998). The norm of this function space can not be expressed in terms of integrals of squared derivatives of integer order.

We now introduce a new function space \(H^\infty_\omega\) that can be seen as the Sobolev space of infinite order:

\[
H^\infty_\omega(Q) = \{ f : f(t) = \sum_{\ell=0}^{\infty} \theta_\ell \phi_\ell(t), \sum_{\ell=0}^{\infty} \rho_i \theta^2_\ell \leq Q; \rho_0 = 1, \rho_{2\ell - 1} = \rho_{2\ell} = e^{\ell^2 \omega^2/2} \}. \tag{8}
\]

where \(\omega\) is a positive constant, and \(\phi_i\)'s are the classical trigonometric basis over \((-\pi, \pi)\). Simple calculation shows that an equivalent definition of \(H^\infty_\omega(Q)\) is

\[
H^\infty_\omega(Q) = \{ f \in L^2(-\pi, \pi) : f \text{ is } 2\pi\text{-periodic, } \sum_{m=0}^{\infty} \frac{\omega^{2m}}{m!2^m} \int_{-\pi}^{\pi} [f^{(m)}(x)]^2 dx \leq Q \}.
\]

From this we can see that \(H^\infty_\omega\) can be seen as the Sobolev space of infinite order, and that the penalty functional \(J_0\) of the periodic Gaussian reproducing kernel as defined in (4) corresponds to the norm of \(H^\infty_\omega(Q)\).

In this paper, we focus on the method of regularization with the periodic Gaussian penalty (4). We will refer to this method as periodic Gaussian regularization. We study the statistical properties of this method both in the situation that \(f \in H^\infty_\omega\) and the situation \(f \not\in H^\infty_\omega\).

By converting the functions into the corresponding sequence of Fourier coefficient, we can see that the white noise problem (5) is equivalent to the following Gaussian sequence model:

\[
y_\ell = \theta_\ell + \epsilon_\ell, \quad \ell = 0, 1, \ldots, \tag{9}
\]

where \(\epsilon_\ell\)'s are independent \(N(0, 1/\mu)\) noises, \(\theta_\ell\)'s are the Fourier coefficients of \(f\). The periodic Gaussian regularization corresponds to

\[
\min \sum_{\ell=0}^{\infty} (y_\ell - \theta_\ell)^2 + \lambda \sum_{\ell=0}^{\infty} \beta_\ell \theta^2_\ell \tag{10}
\]
with $\beta_\ell = e^{\ell^2 \omega^2 / 2}$.

In Section 2 we establish the asymptotic minimax risk (up to the constant) of nonparametric problems in the space $H^\infty(Q)$, and show that the periodic Gaussian regularization achieves this optimal asymptotic risk. In Section 3 we study the asymptotic performance of the periodic Gaussian regularization in the situation where the underlying function to be estimated is in the Sobolev ellipsoid $H^m(Q)$ with unknown $m$ and $Q$, or in the analytic function ellipsoid $A_\alpha(Q)$ with unknown $\alpha$ and $Q$. We show that the method under study is asymptotically minimax in analytic function ellipsoids. For Sobolev ellipsoids $H^m(Q)$, the periodic Gaussian regularization achieves the optimal rate of convergence, and the efficiency in terms of the constant is reasonably high, tending to 1 as $m$ goes to infinity.

In Section 4 we consider choosing the smoothing parameters with the unbiased estimator of risk. The procedure is the well-known Mallows' $C_p$ (Mallows, 1973), sometimes called Mallow's $C_L$ in the literature. Li (1986, 1987) established the asymptotic optimality of $C_p$ in many nonparametric function estimation methods including the method of regularization. Kneip (1994) obtained oracle inequalities for choosing smoothing parameters with $C_p$ in ordered linear smoothers. See also Cavalier, Golubev, Picard, and Tsybakov (2000). These results can be used to study the periodic Gaussian regularization with smoothing parameters chosen by the unbiased risk estimator. We show that the resulting data-driven method retains the good theoretical properties of the periodic Gaussian regularization established in Section 2 and 3. Thus adaptive estimation is achieved for unknown order of smoothness by the periodic Gaussian regularization in the white noise model.

Due to the equivalence between the white noise model and other statistical models, we expect the periodic Gaussian regularization to have good statistical properties in other situations such as regression and generalized regression. In fact, the equivalence results in Brown and Low (1996) shows that the asymptotic results we obtained in Section 2-4 for white noise model applies to the periodic Gaussian regularization in the regression problem (2) with fixed equidistant design. In regression problems with non-equidistant design, the periodic Gaussian regularization in regression does not match up exactly with the periodic Gaussian regularization in the white noise model, therefore our results do not translate directly. However, we believe the results in the white noise model still give insights to the regression problem with general design. In this connection, see Brown and Zhao (2002).

In Section 5, we consider the computation of the periodic Gaussian regularization in regression. The computation does not require the equi-distant design. Some simulations are given in Section 6 to study the finite sample properties of the periodic Gaussian regularization. In particular, the effect of the joint tuning of the smoothing parameters is studied, and the periodic Gaussian regularization is compared with the periodic cubic smoothing spline on four functions of different orders of smoothness. The simulation suggests that the finite
sample performance of the periodic Gaussian regularization is comparable with that of the periodic cubic smoothing spline when the regression function is of moderate smoothness. In the case of a very smooth function, the periodic Gaussian regularization may have an advantage. Summary and discussions are given in Section 7.

Throughout this paper, the expression \( a_n \sim b_n \) means that \( a_n/b_n \to 1 \), as \( n \to \infty \).

## 2 Estimation in the Sobolev space of Infinite Order

In this section we consider the white noise problem in \( H_\omega^\infty(Q) \).

**Theorem 1** The asymptotic minimax risk for nonparametric function estimation in the infinite order Sobolev ellipsoid \( H_\omega^\infty(Q) \) is \( 2\sqrt{2}\omega^{-1}n^{-1}(\log n)^{1/2} \). That is,

\[
\min_\theta \max_{\theta \in H_\omega^\infty(Q)} \sum_{t=0}^\infty E(\tilde{\theta}_t - \theta_t)^2 \sim 2\sqrt{2}\omega^{-1}n^{-1}(\log n)^{1/2},
\]

where the minimization is over all possible estimators \( \tilde{\theta} \).

Notice this asymptotic minimax risk does not depend on \( Q \), but depends on \( \omega \).

The following simple fact is used in the proof of Theorem 1.

**Proposition 1**

\[
\int_0^{\infty} \exp(x^2)dx \sim \exp(a^2)/(2a)
\]

as \( a \to \infty \).

Proof: By the L’Hopital’s rule, we get

\[
\int_0^{\infty} \exp(x^2)dx/[\exp(a^2)/(2a)] = \exp(a^2)/[\exp(a^2) - \exp(a^2)/(2a^2)] \to 1 \quad \text{as} \quad a \to \infty.
\]

\[\square\]

Proof of Theorem 1: By Pinsker’s Theorem (see Johnstone, 1998, Theorem 4.1), the minimax risk in the ellipsoid (8) is the same as the linear minimax risk in (8), and the latter is determined by the difficulty of the hardest rectangular problem. That is, the minimax risk is

\[
R(H_\omega^\infty(Q)) = \max_{\sum p_t \xi_t^2 = Q} \left[ \sum n^{-1} \xi_t^2 (\xi_t^2 + \frac{1}{n})^{-1} \right].
\]

For notational simplicity, we will write \( \xi_t^2 \) as \( \gamma_t \). We use the Lagrange multiplier method to find nonnegative \( \tilde{\gamma}_t \) that maximize \( [\sum (1/n) \gamma_t (\gamma_t + (1/n))^{-1}] \) under the constraint

\[
\sum p_t \gamma_t = Q.
\]

(11)
Let
\[ A = \sum \gamma_\ell (\gamma_\ell + \frac{1}{n})^{-1} - a \sum \rho_\ell \gamma_\ell \]
where \( a \) is a scalar. Maximizing \( A \) under the constraint \( \gamma_\ell \geq 0, \forall \ell \), we get
\[ \gamma_\ell = \left[ b \rho_\ell^{-1/2} - \frac{1}{n} \right]^+ \]
where \( b = (na)^{-1/2} \) is a scalar.

By (11), we have
\[ \sum \rho_\ell \left[ b \rho_\ell^{-1/2} - \frac{1}{n} \right]^+ = Q \]
that is,
\[ 2 \sum_{\ell=1}^{\infty} e^{\ell^2 \omega^2/2} \left[ b e^{-\ell^2 \omega^2/4} - \frac{1}{n} \right]^+ = 2 \sum_{\ell \leq 2 \sqrt{\log(nb)/\omega}} b e^{\ell^2 \omega^2/4} - \frac{1}{n} e^{\ell^2 \omega^2/2} \sim Q \]
From this, we can see that \( nb \to \infty \) when \( n \to \infty \). Using the integral approximation, we have
\[ \frac{2}{n} \int_{0}^{2 \sqrt{\log(nb)/\omega}} (nb)e^{x^2 \omega^2/4} - e^{x^2 \omega^2/2} dx \sim Q. \]

By Proposition 1, we have
\[ \frac{2}{n} \left[ \frac{nb}{n \omega \sqrt{\log(nb)}} - \frac{(nb)^2}{\omega \sqrt{\log(nb)}} \right] = 2nb^2/(\omega \sqrt{\log(nb)}) \sim Q \]
\[ 2 \log(nb) + \log 2 - \log \omega - \frac{1}{2} \log \log(nb) \sim \log n + \log Q \]
\[ \log(nb) \sim \frac{1}{2} \log n \]
Now we have
\[ R(H^\infty_\omega(Q)) = \sum \frac{1}{n} \gamma_\ell (\gamma_\ell + \frac{1}{n})^{-1} \]
\[ = \sum_{\rho_\ell \leq n^2 \omega^2} \frac{1}{n} \left(1 + \frac{1}{n \gamma_\ell} \right)^{-1} \]
\[ = \sum_{\rho_\ell \leq n^2 \omega^2} \frac{1}{n} \left[1 - \frac{1}{n \rho_\ell^{1/2}} \right] \]
\[ \sim 2 \int_{0}^{2 \sqrt{\log(nb)/\omega}} \frac{1}{n} \left[1 - \frac{1}{nb} e^{x^2 \omega^2/4} \right] dx \]
\[ \sim 4 \sqrt{\log(nb)/(n \omega)} - \frac{2}{n^2b \omega \sqrt{\log(nb)/2}} nb \]
\[ \sim 2 \sqrt{2}(\log n)^{1/2}/(n \omega) - 4/(n \omega (\log nb)^{1/2}) \]
\[ \sim 2 \sqrt{2}(\log n)^{1/2}/(n \omega). \]
In the following we consider the periodic Gaussian regularization. The following lemma will be used several times in later proofs.

**Lemma 1** Consider the periodic Gaussian regularization (10) in the white noise model. Denote the estimator by \( \hat{\theta} \). We have \( \sum \text{var} \hat{\theta} \sim 2\sqrt{2} \omega^{-1} n^{-1} (-\log \lambda)^{1/2} \), as \( \lambda \) goes to zero.

Proof: Solving the minimization problem (10), we get the method of regularization estimator \( \hat{\theta}_t = (1 + \lambda \beta_t)^{-1} y_t \). As \( \lambda \) goes to zero, we have

\[
\sum \text{var} \hat{\theta} = \frac{1}{n} \sum (1 + \lambda \beta_t)^{-2}
\]
\[
\sim \frac{2}{n} \sum (1 + \lambda e^{\tau \omega^{2/2}})^{-2}
\]
\[
\sim \frac{2}{n} \int_{0}^{\infty} (1 + \lambda e^{\tau \omega^{2/2}})^{-2} d\tau
\]
\[
= \sqrt{2} n^{-1} \omega^{-1} \int_{\log \lambda}^{\infty} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy
\]
\[
= \sqrt{2} n^{-1} \omega^{-1} \left[ \int_{0}^{\log \lambda} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy + \int_{\log \lambda}^{\infty} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \right].
\]

For the second term in the bracket, we have

\[
0 \leq \int_{0}^{\infty} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \leq (-\log \lambda)^{-1/2} \int_{0}^{\infty} (1 + e^{y})^{-2} dy.
\]

Now let us look at the first term in the bracket. We have, on one hand,

\[
\int_{\log \lambda}^{0} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \leq \int_{\log \lambda}^{0} (y - \log \lambda)^{-1/2} dy = 2(-\log \lambda)^{1/2};
\]
on the other hand,

\[
\int_{\log \lambda}^{0} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \\
\geq \int_{\log \lambda}^{-\log(-\log \lambda)} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \\
\geq (1 + (-\log \lambda)^{-1})^{-2} \int_{\log \lambda}^{-\log(-\log \lambda)} (y - \log \lambda)^{-1/2} dy \\
\sim 2(-\log \lambda)^{1/2}.
\]

Therefore we have

\[
\int_{\log \lambda}^{0} (1 + e^{y})^{-2} (y - \log \lambda)^{-1/2} dy \sim 2(-\log \lambda)^{1/2},
\]
and the conclusion of the lemma follows. \( \triangle \)
Theorem 2  The periodic Gaussian regularization (10) in the white noise model is asymptotically minimax in the infinite order Sobolev ellipsoid $H^\infty(Q)$, if the smoothing parameter $\lambda$ satisfies
\[ \log(1/\lambda) \sim \log n \quad \text{and} \quad \lambda = o(n^{-1}(\log n)^{1/2}). \] (12)

That is,
\[ \min_{\lambda} \max_{\theta \in H^\infty_n(Q)} \sum_{\ell=0}^\infty E(\hat{\theta}_\ell - \theta_\ell)^2 \sim 2\sqrt{2} \omega^{-1} n^{-1}(\log n)^{1/2}, \]
and this asymptotic risk is achieved when (12) is satisfied. Here $\hat{\theta}$ is the method of regularization estimator from (10) with $\beta_\ell = e^{\ell \omega^2/2}$.

The condition (12) is satisfied if $n\lambda_n$ is bounded away from zero and infinity, but is milder. For example, it is satisfied by sequences $\lambda_n = Cn^{-1}(\log n)^{1/2}$ for any constants $C > 0$ and $-\infty < \alpha < 1/2$. The adaptive choice of $\lambda$ is considered in Section 4.

Proof of Theorem 2: The periodic Gaussian regularization estimator is $\hat{\theta}_\ell = (1 + \lambda \beta_\ell)^{-1} y_\ell$. We have, for any $\theta \in H^\infty_n(Q)$,
\[
\sum_{\ell=0}^\infty (E\hat{\theta}_\ell - \theta_\ell)^2 = \sum_{\ell=0}^\infty \lambda^2 \beta_\ell^2 (1 + \lambda \beta_\ell)^{-2} \theta_\ell^2 \leq 1/4 \lambda \sum_{\ell=0}^\infty \beta_\ell^2 \theta_\ell^2 = 1/4 \lambda \sum_{\ell=0}^\infty \nu_\ell \theta_\ell^2 \leq 1/4 \lambda Q;
\]
Hence from Lemma 1 we have, for any $\theta \in H^\infty_n(Q)$,
\[
E \sum_{\ell=0}^\infty (\hat{\theta}_\ell - \theta_\ell)^2 = \sum_{\ell=0}^\infty (E\hat{\theta}_\ell - \theta_\ell)^2 + \sum_{\ell=0}^\infty \text{var} \hat{\theta}_\ell \leq 2\sqrt{2} \omega^{-1} n^{-1} (-\log \lambda)^{1/2} + Q \lambda / 4.
\]
The last quantity is asymptotically equivalent to the asymptotic minimax risk $2\sqrt{2} \omega^{-1} n^{-1} (-\log \lambda)^{1/2}$ under (12). Therefore under (12), the periodic Gaussian regularization estimator is asymptotically minimax. \(\square\)

3  Estimation over Sobolev Spaces and Spaces of Analytic functions

In this section we consider the performance of the periodic Gaussian regularization when the function $f$ to be estimated in the white noise problem belongs to a Sobolev body $H^m(Q)$ with unknown $m$ and $Q$, or a analytic function ellipsoid $A_\alpha(Q)$ with unknown $\alpha$ and $Q$. In these cases, the function to be estimated does not lie in the function space used in the method of regularization.
Theorem 3. Assume \( f \in \mathcal{H}^m(Q) \) with \( m \geq 1 \) in the white noise model (5). Consider the periodic Gaussian regularization estimator \( \hat{\theta}_\ell \) (10) with \( \beta_{2\ell-1} = \beta_{2\ell} = \exp(\ell^2\omega^2/2) \). We have

\[
\min_{\lambda} \max_{\theta \in \mathcal{H}^m(Q)} \sum_{\ell} E(\hat{\theta}_\ell - \theta_\ell)^2 \sim (2m + 1)m^{-2m/(2m+1)}Q^{1/(2m+1)}n^{-2m/(2m+1)}.
\]

This asymptotic risk is achieved when \( \log(1/\lambda)/\omega^2 \sim (mnQ)^{2/(2m+1)}/2 \).

Proof: The estimator is \( \hat{\theta}_\ell = (1 + \lambda \beta_\ell)^{-1}y_\ell \). From Lemma 1, we have

\[
\sum \text{var} \hat{\theta} = (1/n) \sum (1 + \lambda \beta_\ell)^{-2} \sim 2\sqrt{2}\omega^{-1}n^{-1}(-\log \lambda)^{1/2}.
\]

On the other hand, we have

\[
\max_{\theta \in \mathcal{H}^m(Q)} \sum (E\hat{\theta}_\ell - \theta_\ell)^2 = \max_{\theta \in \mathcal{H}^m(Q)} \sum_{\ell=0}^{\infty} (1 + \lambda^{-1} \beta_\ell^{-1})^{-2} \theta_\ell^2 = \max_{\theta \in \mathcal{H}^m(Q)} \sum_{\ell=0}^{\infty} (1 + \lambda^{-1} \beta_\ell^{-1})^{-2} \rho_\ell^{-1}(\rho_\ell \theta_\ell^2).
\]

Here \( \rho_{2\ell-1} = \rho_{2\ell} = 1 + \ell^2 \omega^2 \) are the coefficients in the definition (6) of Sobolev ellipsoid \( \mathcal{H}^m(Q) \). Clearly the maximum is achieved by putting all mass \( Q \) at term \( \ell \) that maximizes \((1 + \lambda^{-1} \beta_\ell^{-1})^{-2} \rho_\ell^{-1} \). That is, the maximum is

\[
Q[\max(1 + \lambda^{-1} \beta_\ell^{-1})^{-2} \rho_\ell^{-1}]. \quad (13)
\]

To evaluate (13), we first find the minimizer of

\[
B_\lambda(x) = (1 + \lambda^{-1} \exp(-x^2 \omega^2/2))^2(1 + x^2 \omega^2) \text{ over } x \geq 0.
\]

Let \( x_0(\lambda) \) be a global minimizer of \( B_\lambda(x) \). It is easy to see that \( x_0(\lambda) \neq \infty \), since \( B_\lambda(\infty) = \infty \). Now let us first show that \( x_0(\lambda) \to \infty \) as \( \lambda \to 0 \). We prove this with the elementary definition of limits. For any \( M > 0 \), we can find \( \bar{x} > M \) such that \( \exp[(\bar{x}^2 - M^2)\omega^2] > 1 + \bar{x}^2 \omega^2 \).

Then \( \lim_{\lambda \to 0} D(\lambda) > 1 \), where

\[
D(\lambda) = [\lambda + \exp(-M^2 \omega^2/2)]^2(1 + x^2 \omega^2)^{-1}.
\]

Therefore there exists \( \delta > 0 \), such that \( D(\lambda) > 1 \) for any \( \lambda < \delta \). On the other hand, for any \( x \leq M, \) we have \( B_\lambda(x) > B_\lambda(\bar{x}) \). Therefore for any \( \lambda < \delta \), we have \( \inf_{x \leq M} B_\lambda(x) > B_\lambda(\bar{x}) \), therefore \( x_0(\lambda) > M \). This shows that \( x_0(\lambda) \to \infty \) as \( \lambda \to 0 \).

Since \( x_0(\lambda) \neq \infty \), we have \( B'_\lambda(x_0) = 0 \). That is,

\[
m^{-1} \omega^2(x_0^2 + x_0^{-(2m-2)}) = 1 + \lambda \exp(x_0^2 \omega^2/2). \quad (14)
\]
Since \( x_0(\lambda) \to \infty \) as \( \lambda \to 0 \), we have
\[
m^{-1} \omega^2 x_0^2 \sim \lambda \exp(x_0^2 \omega^2/2).
\] (15)
\[
x_0^2 \omega^2/2 \sim -\log \lambda
\] (16)

Therefore, by (14) and (15), we have
\[
B_\lambda(x_0) = [1 + (m^{-1} \omega^2 (x_0^2 + x_0^{(2m-2)}) - 1) - 1]^2 (1 + x_0^{2m}) \sim x_0^{2m}.
\]

From this and (16), we see that
\[
Q[\max_\ell (1 + \lambda^{-1} \beta_\ell^{-1})^{-2} \rho_\ell^{-1}] \sim Q x_0^{-2m} \sim Q 2^{-m} \omega^{2m} (-\log \lambda)^{-m}.
\]

Therefore
\[
\max_{\theta \in H_\alpha(Q)} \sum_\ell E(\theta_\ell - \hat{\theta}_\ell)^2 \sim Q 2^{-m} \omega^{2m} (-\log \lambda)^{-m} + 2\sqrt{2} \omega^{-1} n^{-1} (-\log \lambda)^{1/2}.
\] (17)

The conclusion of the theorem then comes from simple calculations. △

**Remark 1** The conclusion of Theorem 3 holds for noninteger \( m > 1 \).

For the ellipsoid \( A_\alpha(Q) \) of analytic functions, we have

**Theorem 4** Assume \( f \in A_\alpha(Q) \) in the white noise problem (5). Consider the periodic Gaussian regularization estimator \( \hat{\theta} \) from (10) with \( \beta_{2k} = e^{\varepsilon_k \omega^2/2} \). We have
\[
\min_\lambda \max_{\theta \in A_\alpha(Q)} \sum_\ell E(\theta_\ell - \hat{\theta}_\ell)^2 \sim 2n^{-1} \alpha^{-1} \log n.
\]

This asymptotic risk is achieved when \( \log(1/\lambda)/\omega^2 = (\log n)^2/(2\alpha^2) \).

The proof of this theorem is similar to that of Theorem 3, and is skipped. It is known that the asymptotic minimax risk in \( A_\alpha(Q) \) is \( 2n^{-1} \alpha^{-1} \log n \). See Johnstone (1998). Therefore Theorem 4 says that the periodic Gaussian regularization is asymptotically minimax in \( A_\alpha(Q) \).

We can study the asymptotic efficiency of the periodic Gaussian regularization, compared with the minimax estimator for nonparametric problems in \( H^m(Q) \). We consider the maximum asymptotic risk over \( H^m(Q) \). We compare the minimum of such asymptotic risk achieved by the periodic Gaussian regularization with the minimax risk over \( H^m(Q) \). This tells how close to the minimax value one can get with the periodic Gaussian regularization. A similar study had been carried out by Carter, Eagleson, and Silverman (1992), who studied the efficiency of the cubic smoothing spline in the second order Sobolev space.
It is well known that the asymptotic minimax risk over $H^m(Q)$ is

$$\left[\frac{2m}{(m + 1)}\right]^{2m/(2m+1)}(2m + 1)^{1/(2m+1)}Q^{1/(2m+1)}n^{-2m/(2m+1)}.$$ 

This can be derived with an argument along the line of the proof of Theorem 1. Figure 1, left panel, gives the ratio between the asymptotic risk of the periodic Gaussian regularization and the minimax risk, when the sample size $n$ is kept to be the same. The right panel gives the efficiency of the periodic Gaussian regularization. The efficiency is calculated in terms of sample sizes need to achieve the same risk. We can see that the efficiency goes to one when the function is very smooth. The lowest efficiency occurs when $m = 1$, and the lowest efficiency is 33.3%. The efficiency when $m = 2$ is 53.3%.

![Figure 1: The efficiency of the periodic Gaussian regularization method.](image)

4 Adaptive choice of the smoothing parameter

In the earlier sections we studied the performance of the periodic Gaussian regularization when the smoothing parameter $\lambda$ has an appropriate rate of decrease. This appropriate rate depends on $m$ (or $\alpha$ or $\omega$) and $Q$, which are generally unknown in practice. In this section we consider the problem of choosing the smoothing parameter with data. We study the common approach of choosing the smoothing parameter through the unbiased estimator of risk (Mallows’ $C_p$). By making use of the oracle inequalities developed in Kneip (1994) (see also Cavalier, Golubev, Picard and Tsybakov, 2000), we show that the estimator chosen by the unbiased estimator of risk has the same asymptotic risk as the estimator with the
optimal (theoretical) smoothing parameter. Thus no asymptotic efficiency is lost due to not knowing \(m\), \(Q\), and \(\omega\).

The number \(\omega\) appears in the asymptotic risk of the periodic Gaussian regularization estimator in the function space \(H^\infty_m(Q)\), but does not play an important role in the asymptotic risk in the function space \(H^m(Q)\), so long as \(\lambda\) is suitably chosen. From (17) we can see that the leading terms in the asymptotic risk in \(H^m(Q)\) depend on \(\omega\) and \(\lambda\) only through \(-\log \lambda/\omega^2\). The asymptotic results suggest that tuning one of \(\lambda\) and \(\omega\) should suffice. For finite sample size, though, it may pay off to tune \(\omega\) as well as \(\lambda\). Usually there is a range of \(\omega\) that works almost equally well if \(\lambda\) is tuned correspondingly, and vice versa. See the simulation in Section 6 for examples. Thus we consider a rough tuning for \(\omega\), just to get to a reasonable range, and a fine tuning over \(\lambda\).

Formally, we take a finite number of \(\omega\)'s: \(\omega_1, \ldots, \omega_S\), and tune \(\lambda\) and \(\omega\) jointly over \(\lambda\) and \(\omega, \in \{\omega_1, \ldots, \omega_S\}\). For asymptotic consideration, a range of \([0, 1]\) for \(\lambda\) suffices, since asymptotically \(\lambda\) should go to zero. In practice we may use a slightly larger range.

The tuning is based on the unbiased estimator of risk. Writing \(\tau_\ell = (1 + \lambda_\ell \beta_\ell)^{-1}\), our estimator is \(\hat{\theta}_\ell = \tau_\ell y_\ell\). We can express the risk of our estimator as

\[
\sum E(\hat{\theta}_\ell - \theta_\ell)^2 = \frac{1}{n} \sum_{\ell=0}^{\infty} \tau_\ell^2 + \sum_{\ell=0}^{\infty} (1 - \tau_\ell)^2 \theta_\ell^2.
\]

Now an unbiased estimator for \(\theta_\ell^2\) is \(y_\ell^2 - (1/n)\). Plugging in we get that

\[
\sum_{\ell=0}^{\infty} \left[ (\tau_\ell^2 - 2\tau_\ell)(Y_\ell^2 - 1/n) + (1/n)\tau_\ell^2 \right] = \sum_{\ell=0}^{\infty} \left[ (\tau_\ell^2 - 2\tau_\ell)Y_\ell^2 + (2/n)\tau_\ell \right]
\]

is an unbiased risk estimator of \(\sum E(\hat{\theta}_\ell - \theta_\ell)^2 - \sum \theta_\ell^2\). We choose \(\lambda^*\) and \(\omega^*\) that minimizes the unbiased risk (18), and use the corresponding periodic Gaussian regularization estimator \(\hat{\theta}^*\). Kneip (1994) studied the adaptive choice among ordered linear smoothers with the unbiased risk estimator. A family of ordered linear smoothers satisfy the condition that for any member \(\hat{\theta}_\ell = \tau_\ell y_\ell\), \(\ell = 0, 1, \ldots\) of the family, we have \(\tau_\ell \in [0, 1]\), \(\forall \ell\); and for any two members of the family \(\tau_\ell y_\ell\) and \(\tau_\ell' y_\ell\), \(\ell = 0, 1, \ldots\), we have either \(\tau_\ell \geq \tau_\ell', \forall \ell\), or \(\tau_\ell \geq \tau_\ell, \forall \ell\). It is easy to check that for any fixed \(\omega \in \{\omega_1, \ldots, \omega_S\}\), the method of regularization estimators with varying \(\lambda\) form a family of ordered linear smoother. Kneip (1994) studied this situation, and gave the following result (recast in the Gaussian sequence model setting in Cavalier, Golubev, Picard and Tsybakov; 2000)

\[
\sum E(\hat{\theta}^*_\ell - \theta_\ell)^2 \leq (1 + O(B^{-1})) \min_{\lambda, \omega_s} \left\{ \sum E(\hat{\theta}_\ell - \theta_\ell)^2 \right\} + n^{-1}O(B), \quad \forall \theta \in \ell^2, \forall B > 0.
\]

**Theorem 5** For the periodic Gaussian regularization estimator \(\hat{\theta}^*\) chosen by the unbiased estimator of risk, we have

\[
\sup_{\theta \in H^\infty_m(Q)} \sum_{s=0}^{\infty} E(\hat{\theta}^*_s - \theta_s)^2 \sim 2\sqrt{2}\omega_s^{-1} n^{-1}(\log n)^{1/2}, \quad \forall s \in \{1, \ldots, S\}.
\]
\[
\sup_{\theta \in H^m(Q)} \sum_{\ell \in \mathbb{Z}} E(\hat{\theta}_\ell^* - \theta_\ell)^2 \sim (2m + 1)m^{-2m/(2m+1)}Q^{1/(2m+1)} n^{-2m/(2m+1)}.
\]
\[
\sup_{\theta \in A_n(Q)} \sum_{\ell \in \mathbb{Z}} E(\hat{\theta}_\ell^* - \theta_\ell)^2 \sim 2n^{-1} \alpha^{-1} \log n.
\]

Proof: By (19), we have
\[
\sup_{\theta \in H^m(Q)} \sum_{\ell \in \mathbb{Z}} E(\hat{\theta}_\ell^* - \theta_\ell)^2 \leq (1 + O(B^{-1})) \sup_{\theta \in H^m(Q)} \min_{\lambda, \omega_s} \left\{ \sum_{\ell \in \mathbb{Z}} E(\hat{\theta}_\ell - \theta_\ell)^2 \right\} + n^{-1} O(B)
\]
\[
\leq (1 + O(B^{-1})) \min_{\lambda, \omega_s} \sup_{\theta \in H^m(Q)} \left\{ \sum_{\ell \in \mathbb{Z}} E(\hat{\theta}_\ell - \theta_\ell)^2 \right\} + n^{-1} O(B).
\]

Similar inequalities holds for \(H_{\omega_s}^\infty(Q)\) and \(A_n(Q)\). Now take \(B = (\log n)^{1/3}\), the conclusion of the theorem follows from Theorem 1-4 and the fact that \(\omega_s \in \{\omega_1, ..., \omega_s\}\) has finitely many possibilities. \(\triangle\)

Therefore the adaptive periodic Gaussian regularization estimator \(\hat{\theta}^*\) is asymptotically minimax in \(H_{\omega_s}^\infty(Q)\) and \(A_n(Q)\), and achieves the optimal rate in \(H^m(Q)\). The asymptotic efficiency is the same as that given in Section 3. Hence the estimator adapts to any unknown order of smoothness.

5 Computation of Periodic Gaussian Regularization in Regression

In order for the periodic Gaussian regularization in the regression and the generalized regression to be practically computable, we need the form of the reproducing kernel corresponding to the penalty functional \(J_p(f)\). That is, the reproducing kernel of \(H_\sigma^\infty\). Smola, Schölkopf, and Müller (1998) gave the following expression for the periodic Gaussian reproducing kernel:
\[
R(s, t) = (1/\pi) \sum_{\ell=1}^{\infty} \exp(-\ell^2 \omega^2/2) \cos(\ell(s - t)). \tag{20}
\]

Due to the fast decay of the sequence \(\exp(-\ell^2 \omega^2/2)\), it is possible to approximate the series (20) with finitely many terms. However, an alternative formula of the kernel (20) is better suited for computation. We first state a lemma due to Williamson, Smola, and Schölkopf (2001).

**Lemma 2** Let \(V(s - t)\) be a reproducing kernel with \(V: R \rightarrow R\) being an even function. Let \(V_\nu(s) = \sum_{k=-\infty}^{\infty} V(s - k\mu)\).
Then
\[ V_\nu(s - t) = \frac{\sqrt{2\pi}}{\nu} \tilde{V}(0) + \sum_{k=1}^{\infty} \frac{2}{\nu} \sqrt{2\pi} \tilde{V}(2k\pi/\nu) \cos(2k\pi(s - t)/\nu), \]

where \( \tilde{V} \) is the Fourier transformation of \( V \).

Define \( G^\infty(r) = \sum_{k=-\infty}^{\infty} G(r - 2k\pi) \). It follows directly from Lemma 2 that \( G^\infty(s - t) \) is the reproducing kernel (20) corresponding to the periodic Gaussian regularization.

The function \( G^\infty \) is defined as an infinite series, but is easy to calculate numerically. Since \( G^\infty \) is \( 2\pi \)-periodic, we only need to calculate \( G^\infty(s) \) for \( s \in [-\pi, \pi] \). In this range \( G^\infty(s) \) is very close to \( G(s) \) for small to moderate \( \omega \) due to the fast decay of \( G(s) \). For \( \omega \leq 1 \), a quick examination gives:

\[ 0 < G^\infty(s) - G(s) < 0.003, \quad \forall s \in [-\pi, \pi]. \]

For \( \omega \leq 1/2 \), the difference is within \( 2.2 \times 10^{-9} \). Therefore \( G(s) \) can be used as a quick approximation of \( G^\infty(s) \). Furthermore, if we define

\[ G^J = \sum_{k=-J}^{J} G(s - 2k\pi), \]

then we have

\[ 0 < G^\infty(s) - G^J(s) < 2.1 \times 10^{-20}, \quad \forall s \in [-\pi, \pi] \quad \text{for} \quad \omega \leq 1. \]

For \( \omega > 1 \), we choose positive integer \( J \) such that \( 2J + 1 \geq 3\omega \), then \( 0 < G^\infty(s) - G^J(s) < 10^{-20}, \quad \forall s \in [-\pi, \pi] \). Therefore \( G^J(s) \) is an easily computable proxy of \( G^\infty(s) \). The accuracy is probably good for any practical purposes.

Now consider the periodic Gaussian regularization in the regression problem (2) with the empirical loss being \( \sum_{j=1}^{n}(y_j - f(x_j))^2 \). Here we assume \( x_j \in (-\pi, \pi), j = 1, \ldots, n \), and the regression function \( f \) is \( 2\pi \)-periodic. The theory of reproducing kernel Hilbert space guarantees that the solution to the method of regularization falls in a finite dimensional space spanned by \( G^\infty(x_j, \cdot) \). That is, we can write \( \hat{f}(x) = \sum_{j=1}^{n} \hat{c}_j G^\infty(x_j - x) \), and the penalized regression (1) becomes

\[ (y - G^\infty c)'(y - G^\infty c) + \lambda c'G^\infty c, \]

where, with little risk of confusion, we write \( y = (y_1, \ldots, y_n)' \), \( c = (c_1, \ldots, c_n)' \), and \( G^\infty \) is the \( n \times n \) matrix \( (G^\infty(x_i - x_j)) \). The solution can then be found to be \( \hat{c} = (G^\infty + \lambda I)^{-1}y \). In order to compute the solution as well as Mallows' \( C_p \) for tuning the smoothing parameters, we use the eigenvalue-eigenvector decomposition \( G^\infty = VDV' \), where \( D \) is the diagonal matrix of eigenvalues, and \( V \) is the orthonormal matrix of eigenvectors. Let

\[ T = D(D + \lambda I)^{-1}. \]
Then \( \hat{f} = SY \), where \( S = VTV' \). Mallows' \( C_p \) in this context is \( \|y - \hat{f}\|^2/n + (2/n)\text{tr}(S) \). Notice the computation of the periodic Gaussian regularization in regression does not require equi-distant design.

It is possible to leave the constant term in the regression function unpenalized, as is commonly done in practice with smoothing splines and Gaussian regularization. This is equivalent to having \( \beta_0 = 0 \) in (10), and the asymptotic results do not change. The penalized regression can be written as

\[
\min_{f, b} \sum_{j=1}^{n} (y_j - (f(x_j) + b))^2 + \lambda J_0(f).
\]

In this case the theory of reproducing kernel Hilbert space dictates that the solution can be expressed as \( \hat{f} = G^\infty e + \hat{e}c \), where \( e = (1, ..., 1)' \). In the case of equidistant sample inputs, we can see that \( e \) is an eigenvalue of \( G^\infty \), since \( G^\infty \) is periodic and even. In this case the computation is very similar to the case above with constants penalized: one simply replaces the diagonal element of \( T \) in (21) corresponding to the eigenvalue \( e \) by 1, and continues the computation with the new \( T \).

## 6 Simulations

We conduct some simulations to study the finite sample properties of the periodic Gaussian regularization in regression. Consider the regression problem (2) with the following four functions on \([-\pi, \pi] \):

\[
\begin{align*}
f_1(x) &= \sin^2(x)1_{(x \geq 0)}; \\
f_2(x) &= -x - \pi + 2(x + \pi/2)1_{(x \geq -\pi/2)} + 2(-x + \pi/2)1_{(x \geq \pi/2)}; \\
f_3(x) &= 1/(2 - \sin(x)). \\
f_4(x) &= 2 + \sin(x) + 2\cos(x) + 3\sin^2(x) + 4\cos^3(x) + 5\sin^3(x);
\end{align*}
\]

The plots of the four functions are given in Figure 2. These are all 2\( \pi \)-periodic functions. The first function has only the second order of smoothness. The second function has only the first order of smoothness. The third function is infinitely smooth. The fourth function is even smoother: its Fourier series only contains finitely many terms. In all of our simulations the sample size is taken to be 100. All simulations are done in Matlab.

First we study the effect of the joint tuning of \( \lambda \) and \( \omega \). We look at the regression problem (2) with the first regression function \( f_1(x) \). In the first simulation we take the sample points to be equidistant in \([-\pi, \pi]\). The scatter plot is shown in Figure 3, top left panel. We use the periodic Gaussian regularization to do the estimation for \( \omega = (k_1/5)^{(1/2)} \),
\( \lambda = \exp(-k_2/5), \, k_1 = 1, \ldots, 100, \, k_2 = 1, \ldots, 100 \). For each combination of \( \omega \) and \( \lambda \) we calculate the solution \( \hat{f}_{\lambda, \omega} \), and the mean squared error \( (1/n) \sum_j [\hat{f}_{\lambda, \omega}(x_j) - f(x_j)]^2 \). The bottom left panel of Figure 3 gives the corresponding contour plot of the mean squared error. The \( x- \) and \( y- \) axes for the contour plot are \( k_1 \) and \( k_2 \), which are proportional to \( \omega^2 \) and \( -\log \lambda \). Let the minimum of the mean squared error be \( a \). The levels in the contour plot are at \( 1.01a, 1.05a, 1.1a, 1.2a, 1.5a, 2a, 3a, 4a, 5a, 6a \). We used these levels to focus on the behavior of the mean squared error around its minimum. It is clear that the contour levels are almost straight lines, indicating that the mean squared error are almost the same when \( -\log \lambda \) varies linearly with \( \omega^2 \). This agrees with what is suggested by the asymptotic results.

Similar to any method of regularization, the periodic Gaussian regularization does not depend on the \( x \) being equidistant. The same phenomenon in the joint tuning of \( \lambda \) and \( \omega \) appears when the inputs \( x \)'s are not equidistant. We run the same simulation with non-equidistant \( x \), and the corresponding scatter plot and the contour plot are given in the right panels of Figure 3. The non-equidistant \( x \) values are generated by taking the fractional part of a normal variate with mean 1/4 and standard deviation 1/4, and then scale the \([0, 1]\) interval to \([-\pi, \pi]\).

We run the same experiment with the other functions \( f_2, f_3, \) and \( f_4 \), and the same observation about the joint tuning of \( \lambda \) and \( \omega \) is made in these experiments. This supports our strategy of a rough tuning for \( \omega \) and a fine tuning over \( \lambda \).

Next we compare the periodic Gaussian regularization with the periodic cubic smoothing spline for regression on the circle on the four functions in Figure 2. The periodic cubic smoothing spline is the solution to

\[
\sum_{j=1}^{n} (y_j - f(x_j))^2 + \lambda \int_{-\pi}^{\pi} |f''(t)|^2 dt.
\]

This penalty corresponds to the second order Sobolev space, but leaves the linear functions unpenalized. For an introduction to the periodic cubic smoothing spline, see Wahba (1990), or Gu (2002).

We fix \( x \) to be equidistant in \((-\pi, \pi)\) in our comparison. We generate \( y \)'s according to the regression model (2) with the four functions we consider. In both the periodic Gaussian regularization and the periodic cubic smoothing spline, the smoothing parameters are chosen according to Mallows' \( C_p \). We search the minimal point of Mallows' \( C_p \) over \( \omega = 0.3k_1 - 0.1 \), for \( k_1 = 1, \ldots, 10 \); and \( \lambda = \exp(-0.4k_2 + 7) \), for \( k_2 = 1, \ldots, 50 \), for the periodic Gaussian regularization; and over \( \lambda = \exp(-0.4k_2 + 7) \), for \( k_2 = 1, \ldots, 50 \), for the smoothing spline. We use the chosen smoothing parameter(s) to compute the solutions. For each generated dataset, we calculate the mean squared error of the periodic Gaussian regularization and the periodic cubic smoothing spline.
We run the simulation 100 times. The averaged mean squared errors over the 100 runs are summarized in table 1. For each regression function, a two-sided paired t-test is performed to compare the periodic Gaussian regularization and the periodic cubic smoothing spline based on the 100 runs. For the first function, the p-value is 0.49; for the second function, the p-value is 0.06, and it seems the smoothing spline may perform better; for the third function, the p-value is 0.9; for the fourth function, the p-value is very close to 0, the periodic Gaussian regularization performed significantly better: we can see the mean squared error of the periodic Gaussian regularization is 22% less than that of the periodic smoothing spline.

Table 1: Averaged mean squared error over 100 runs, for the periodic cubic smoothing spline, the periodic Gaussian regularization, and the periodic Gaussian regularization with constant left unpenalized, on four different functions of varying order of smoothness.

7 Summary and discussion

In this paper we study the method of regularization with the periodic Gaussian kernel. Asymptotically, the method adapts to unknown order of smoothness, and is efficient compared with the minimax risk when the underlying function is reasonably smooth. The smoothing parameters in the periodic Gaussian regularization can be chosen adaptively without loss of asymptotic efficiency. Limited experiments in finite sample case suggest that the performance of the periodic Gaussian regularization is comparable to that of the periodic cubic smoothing spline when the underlying regression function is reasonably smooth, and the periodic Gaussian regularization may have some advantage over the periodic cubic smoothing spline when the regression function is very smooth. This agrees with the asymptotic analysis, since it is well known that the cubic smoothing spline does not adapt to high order of smoothness.

The Gaussian reproducing kernel is commonly used in practice and has been successful in empirical studies. Our study on the periodic Gaussian reproducing kernel gives a partial
explanation of the success of Gaussian reproducing kernel in practice, as we expect the Gaussian reproducing kernel to have similar properties to its periodic counterpart. When we applied the non-periodic version of the Gaussian kernel to the examples in our simulation, the results are slightly inferior to the periodic version. This is to be expected, as the non-periodized version does not take advantage of the fact that the functions in the simulation are periodic. However, the difference is not large. The average mean squared errors are 0.0736, 0.0679, 0.0559, and 0.1198.

The penalty functional $J_0$ in periodic Gaussian regularization corresponds to the norm of the infinite order Sobolev space $H^\infty_\alpha$. It is also possible to consider the method of regularization with the penalty functional being the norm of the space $A_n$ of analytic functions. This penalty can not be written in terms of integrals of squared derivatives of integer order, but can be written in terms of derivatives of fractional order. In the Gaussian sequence model setting, the method of regularization with the analytic function space penalty is equivalent to the method of regularization (10) with $\beta_\ell = \exp(\alpha \ell)$. Similar asymptotic results as derived for the periodic Gaussian regularization can be derived for this alternative regularization: the method adapts to Sobolev space $H^m$ with unknown smoothness $m$. It is also possible to give an explicit expression of the reproducing kernel. In fact, the reproducing kernel is (20) with $\exp(-\omega^2 \ell^2/2)$ replaced by $\exp(-\alpha \ell)$. An equivalent form of this reproducing kernel is $E^\infty(s - t)$, with $E^\infty(r)$ defined as $E^\infty(r) \equiv \sum_{k=\pm\infty} E(r - 2k\pi)$, and $E(r) = \alpha / [\pi (r^2 + \alpha^2)]$ is the Cauchy density function. This form follows from Lemma 2. Unlike the periodic Gaussian kernel case, the decay of $E(x)$ is slow, and it does not seem practical to use the form $E^\infty(s - t)$ for computation. On the other hand, it might be possible to calculate the reproducing kernel with the series in (20) with $\exp(-\alpha \ell)$.

References

Figure 2: The regression functions used in the simulations. The first function has only the second order of smoothness. The second function has only the first order of smoothness. The third function is infinitely smooth. The fourth function has a Fourier series that only contains finitely many terms.
Figure 3: The top panels are the scatter plots of the data generated from the regression model (2) with the regression function \( f_1(x) \). Left: equidistant case; Right: non-equidistant case. The bottom panels are the corresponding contour plots of the mean squared errors of the periodic Gaussian regularization. The \( x \)- and \( y \)-axes for the contour plots are proportional to \( \omega^2 \) and \(-\log \lambda \), respectively. We can see that in both cases, the contour levels are very close to straight lines.
